

AI for ambulance prioritization: From model to practice

Douglas Spangler

Business developer, Emergency Medical Technician, PhD candidate

Region Uppsala, Sjukvårdens Larmcentral

Background

- Vinnova grant 2017 for development of ML models based on an existing decision support system

A validation of machine learning-based risk scores in the prehospital setting

Douglas Spangler , Thomas Hermansson, David Smekal, Hans Blomberg

Published: December 13, 2019 • <https://doi.org/10.1371/journal.pone.0226518>

- Project ended in 2021 – But still want to implement the model!
- Currently: Home stretch of RCT data collection

Allmän åldring x

ABCDE

B Andnöd
 Ja Nej

C Blek och kallsvettig som tecken på cirkulatorisk chock
 Ja Nej

D Medvetandepåverkad
 Ja Nej

D Patienten kan prata
 Ja Nej

D Patienten kan stå upp
 Ja Nej

A Sväljningssvårigheter, grötigt tal, dreglar
 Ja Nej

D Kraftnedsättning/förlamning
 Ja Nej

O Onset

P Palliation/provocation

The problem

- Too many patients, not enough ambulances – Who should go first?
- Study goals:
 - Ensure patient safety
 - Generate high-quality evidence
 - Open source implementation
- How to clinically evaluate a novel triage algorithm with no budget?

Some lessons

- Study population selection
- Outcome definition
- Intervention & study design
- Estimand selection & Power calculation
- Ethics & practice
- Future directions for development

Prehospital populations

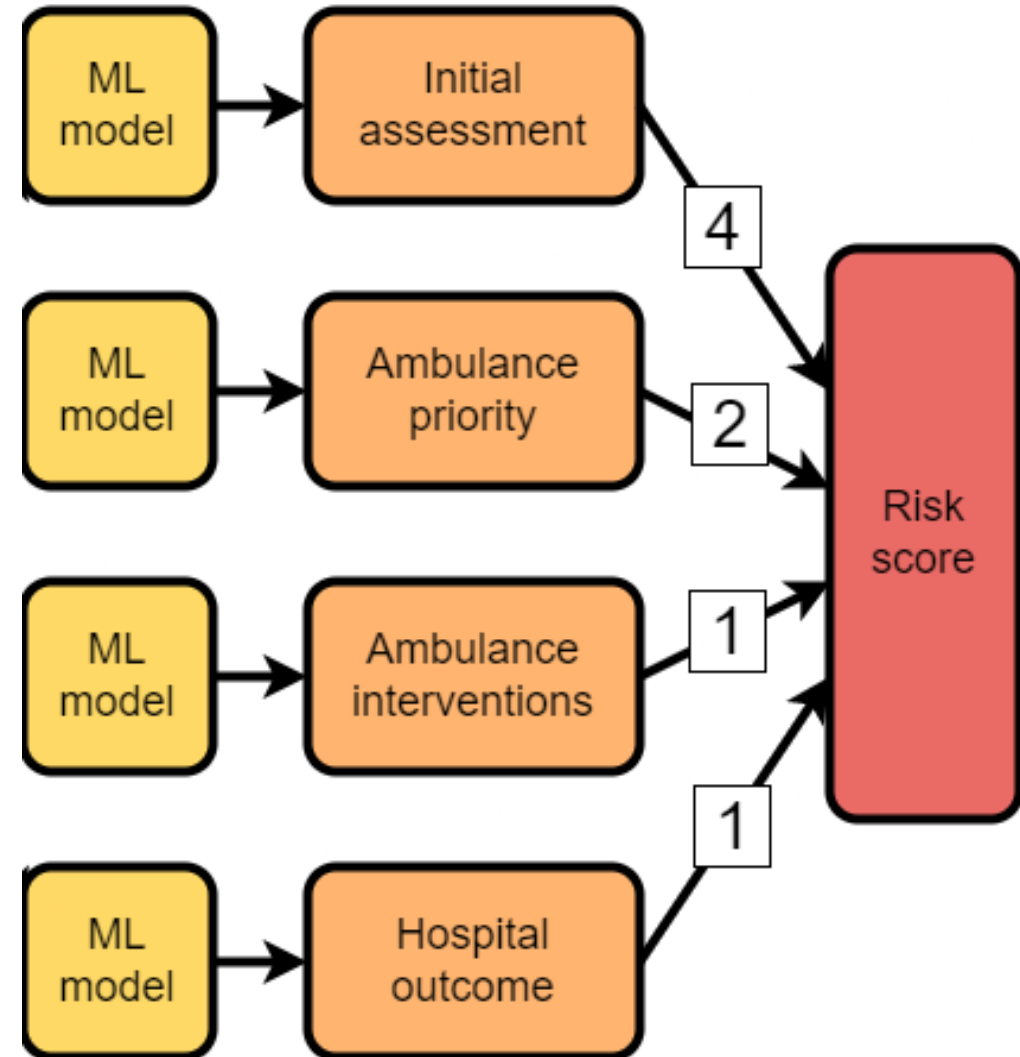

- Higher acuity
 - Rapid assessment
 - High sensitivity
 - Specific, rare syndromes
 - Simple outcome definitions

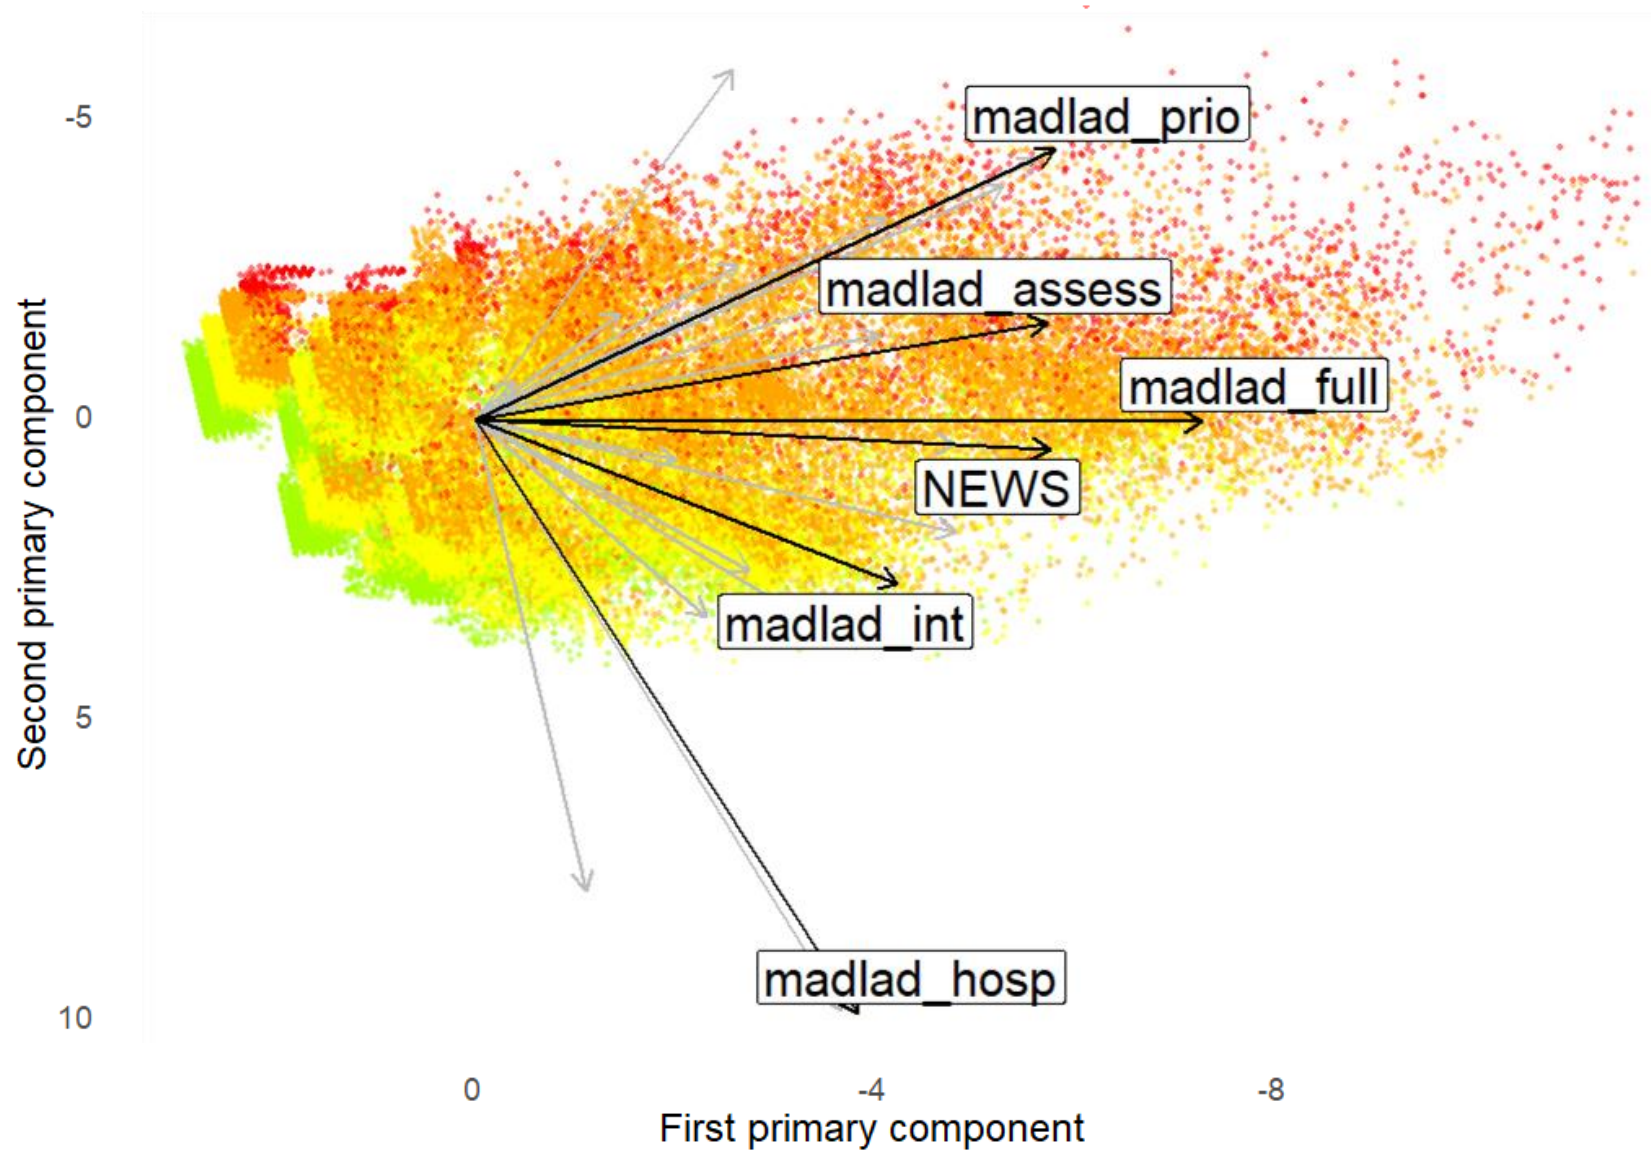

- Lower acuity
 - Looser time constraints
 - Need for differentiation
 - Comparisons across etiologies
 - Tricky to define relevant outcomes

Outcome definition

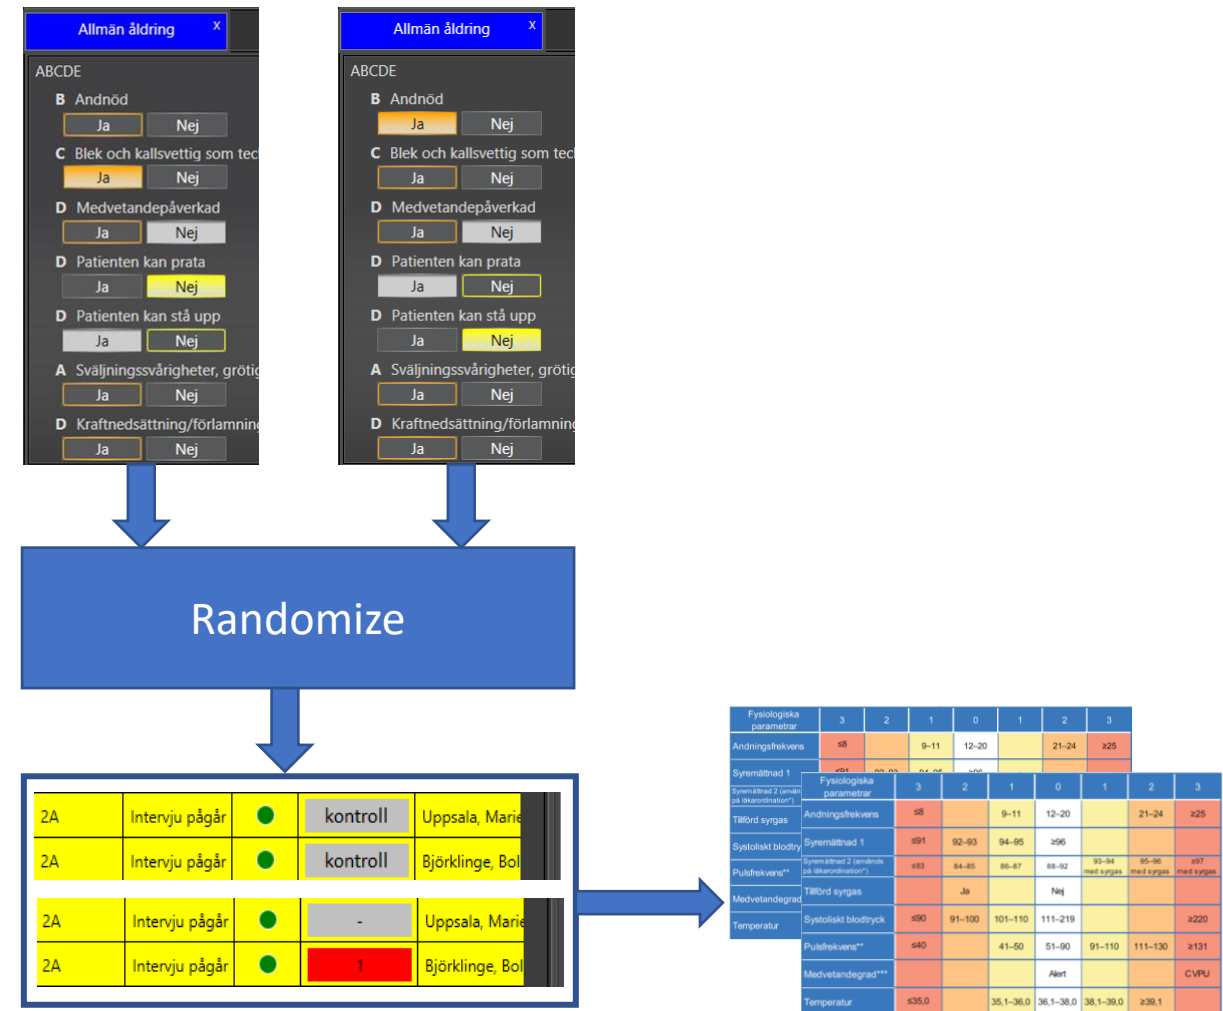

- Define a set of outcome measures which correspond with:
 - Qualitative, clinical domain knowlege
 - Existing patient risk scoring tools
- Study Outcome
 - Correlated with, but not caused by model outcomes

Machine learning Assisted Differentiation of Low-Acuity patients at Dispatch (MADLAD): A Randomized Control Trial

- **Question:** Does information from a ML model improve triage accuracy at dispatch?
- **Sample:** 1500 "resource constrained situations" in Uppsala and Västmanland
- **Method:** RCT – With or without information from the tool

Estimand definition

- Initially: Difference in NEWS score between prioritized vs. Non-prioritized patients
 - How to handle multiple non-prioritized patients?
 - Odd distribution of NEWS scores – Ratio scale? What does the difference mean?
- Finally: Dichotomized outcome
 - Loss of power to achieve more interpretable results

Power estimation

- Relatively simple to estimate model accuracy – But no data on historical nurse decisions!
- Simulate accuracy of comparisons between 2A and 2B assignments
- Assumed 100% compliance with model

Ethics approval

- Study design minimizes risk
 - All patients get an ambulance eventually!
 - ... But also minimizes potential benefits
- Approval for "Assumed consent": Send patients information afterwards and provide an opportunity to opt-out
- Initially high rates of opt-out – Reformulation of Informed consent letter & Form

Quality Assurance

- How to continuously ensure patient safety without exposing study results?
- Evaluate differentiation between **individuals** throughout study
- Evaluate compliance (ca 80%)

Further Development

- Model development
 - Additional structured data from patient history
 - Parsing audio data – Good open models now available (Whisper)
- Regulatory issues
 - How to handle regulatory approval without profit motive?
 - Continued use as "Self developed medical device":
 - In Sweden: Same documentation as CE marking, but no certification process
- Applications
 - Non-randomized implementation
 - Ambulance referral risk calculator ([link](#))

Cheers!
